Power-law

Why scale-free?

Normalizing

Divergence

Distance

- Usually we plot a power-laws on log-log scale. Why?

- Power-law:  $p(k) \simeq ck^{-\gamma}$ ,

$$\rightarrow \ln p(k) \simeq \ln c - \gamma \cdot \ln k.$$

- In a log-log plot

$$x \rightarrow \ln k,$$

$$y = f(x) \rightarrow \ln p(k),$$

$$\rightarrow f(x) = \ln c - \gamma \cdot x$$

- Thus, on log-log scale a power-law looks like a linear function, with a slope equal to  $\gamma$ .

## Scale-free networks

- A network is called **scale-free** if the tail of its degree distribution **decays as a power-law**,

$$p(k) \sim k^{-\gamma}.$$

- The exponent  $\gamma$  is often referred to as the node degree exponent or node degree decay exponent.

## Scaling function

**Definition:** a function  $F(x)$  is **scaling** if

$$F(a \cdot x) = g(a) \cdot F(x),$$

thus, changing the argument is equivalent to multiplying  $F(x)$  with a constant.

## Power-laws are scaling

Assume  $F(x) = b \cdot x^\gamma$ .

$$\rightarrow F(a \cdot x) = b \cdot (a \cdot x)^\gamma = b \cdot a^\gamma \cdot x^\gamma = a^\gamma \cdot b \cdot x^\gamma = a^\gamma \cdot F(x).$$

(In addition, it can be proven that all scaling functions are power-laws).

Divergence  
Distance

How to turn  $p(k) \sim k^{-\gamma}$  into a normalized distribution?

$$p(k) = Ck^{-\gamma} \rightarrow C = \frac{1}{\sum_k k^{-\gamma}}$$

Assuming  $k > 0$  (no isolated nodes),  $C^{-1}$  is actually the Riemann Zeta function!

The Riemann Zeta function:

$$\zeta(s) \equiv \sum_{n=1}^{\infty} n^{-s} = \frac{1}{1^s} + \frac{1}{2^s} + \frac{1}{3^s} + \dots$$

$$\rightarrow p(k) = \frac{k^{-\gamma}}{\zeta(\gamma)}.$$
